## Topic - 9

Super() → keyword

super () → when a child and parent class both have a method with same name, the method overrides the parent method.

Super() → is used inside the child class to call the parent class version of that method.

Super():-

- Inside a constructor
- Inside a method
- Inside To access parent variable.

① Super() in constructor:-

when parent and child both have constructor (__init__) child constructor holds parent constructor.

To call parent constructor, use super().__init__().

#code

```
class parent:
    def __init__(self):
        print("parent constructor")

class child(Parent):
    def __init__(self):
        print("child constructor")
        super().__init__()   #calling parent class constructor..

obj = child()
```

Scanned with OKEN Scanner

without super() contructor we will only get the childclass name.

(2) super() methods:

If both parent and child have same method name. child method overrides parent method.

" super().<methodnames>()

ex

```
class parent:
    def show(self):
        print(" parent show method")

class child(parent):
    def show(self):
        print(" child show method")
        super().show()

obj=child()
obj.show
```

[both methods outputs occur].

③ Super() to access parent variables:

Parent class variable can be accessed in child class by super().

```
class parent:
    def __init__(self):
        self.name= "Ravi"

class child(parent):
    def __init__(self):
        super().__init__()
        print(self.name)

obj = child()
```
